

# SynDiff Synthetic Benchmark — Live Progress

2026-07-12 19:42:10 CEST

**942/942** jobs complete (100.0%)

$S = I(X_1; Y | X_2) - I(X_1; Y)$  in nats;  $S > 0$  synergy-dominant,  $S < 0$  redundancy-dominant. SynDiff (ours) vs prior estimators.

## Dataset construction

### Phase 1 — Gaussian (closed-form ground truth)

Scalar base:  $X_1, X_2 \sim \mathcal{N}(0, 1)$  with  $\text{corr}(X_1, X_2) = \rho$ ; label  $Y = X_1 + X_2 + \sigma_y \varepsilon$ ,  $\varepsilon \sim \mathcal{N}(0, 1)$ . Thus  $\text{Var}(Y) = 2 + 2\rho + \sigma_y^2$  and  $\text{Cov}(X_i, Y) = 1 + \rho$ . To lift to  $d$  dimensions the informative scalar is padded with  $d - 1$  i.i.d.  $\mathcal{N}(0, 1)$  coordinates and rotated by a fixed per-seed orthogonal matrix  $Q_i$  (one per variable). Rotation and independent padding preserve mutual information, so  $S$  is unchanged and the closed form carries over. Ground truth is computed from the  $3 \times 3$  covariance via  $I = \frac{1}{2} \log(\det \Sigma_A \det \Sigma_B / \det \Sigma_{AB})$  and the analogous conditional form. Cells sweep  $\rho \in \{-.9, \dots, .9\}$ ,  $\sigma_y \in \{.1, 1\}$ ,  $n \in \{1\text{k}, \dots, 100\text{k}\}$ ,  $d \in \{1, 8, 32, 128\}$ .

### Phase 2 — discrete U/R/S (mixture-density MC truth)

Latent sources  $s_1, s_2, s_3 \sim \text{Unif}\{0, \dots, Q - 1\}$  with  $Q = 8$ . Encodings  $X_i = W_i \text{onehot}(s_i) + \sigma_{\text{enc}} \mathcal{N}(0, I_{32})$  with orthonormal  $W_i \in \mathbb{R}^{32 \times 8}$  frozen per seed. Regimes ( $X_1$  always encodes  $s_1$ ): **UNIQUE**  $Y = s_1$ ; **REDUNDANT**  $Y = s_1$  and  $X_2$  also encodes  $s_1$ ; **SYNERGY1**  $Y = (s_1 + s_2) \bmod Q$  with  $X_2 \sim s_2$ ; **SYNERGY2**  $Y = (s_3 + (s_1 + s_2) \bmod Q) \bmod Q$  with  $X_2 = [\text{enc}(s_2) | \text{enc}(s_3)] \in \mathbb{R}^{64}$ ; **INDEPENDENT**  $Y = s_3$ . The  $\lambda$ -dial mixes the SYNERGY1 and REDUNDANT rules per sample (Bernoulli( $\lambda$ )). Ground truth is the exact  $S = I(X_1; X_2, Y) - I(X_1; X_2) - I(X_1; Y)$  obtained by Monte Carlo over the enumerable Gaussian-mixture components (matches the discrete limit as  $\sigma_{\text{enc}} \rightarrow 0$ :  $\pm \log Q$  for pure synergy/redundancy, 0 for unique/independent).

## Method: SynDiff

Target  $S = I(X_1; Y | X_2) - I(X_1; Y)$  in nats. By the symmetry of interaction information this equals  $I(X_1; X_2 | Y) - I(X_1; X_2)$ , which the four-mask form below estimates directly. **VP schedule**:  $\beta(t) = 0.1 + 19.9t$ ,  $B(t) = \int_0^t \beta = 0.1t + 9.95t^2$ , signal  $k(t) = e^{-B/2}$ , noise  $\sigma^2(t) = 1 - e^{-B}$ , weight  $w(t) = \beta(t)/(2\sigma^2(t))$ . A single noise-prediction network  $\hat{e}(x_{1,t}, t, \text{cond})$  (*MaskedCondMLP*: Fourier- $t$  features  $\oplus$  per-slot conditioning embeddings each with a learned NULL token;  $4 \times 512$  SiLU) is trained to denoise  $X_1$  while each conditioning slot ( $X_2, Y$ ) is independently dropped to its NULL token with probability 0.15. EMA weights (decay 0.999) are used at evaluation. **Four-mask estimator**. Per evaluation triple and per stratified time  $t$  ( $K=16$  strata on  $[10^{-3}, 1]$ ) with *one shared* noise draw  $\varepsilon$  and  $x_{1,t} = k(t)x_1 + \sigma(t)\varepsilon$ :

$$\begin{aligned} e_1 &= \hat{e}(x_{1,t}, t, x_2, y), & e_2 &= \hat{e}(x_{1,t}, t, \emptyset, y), \\ e_3 &= \hat{e}(x_{1,t}, t, x_2, \emptyset), & e_4 &= \hat{e}(x_{1,t}, t, \emptyset, \emptyset), \end{aligned}$$

$$\text{integrand}(t) = w(t)(\|e_1 - e_2\|^2 - \|e_3 - e_4\|^2).$$

Per-sample  $\hat{S} = (1 - 10^{-3}) \overline{\text{integrand}_t}$ ; the estimate is the mean over  $10^4$  fresh triples with a 1000-sample bootstrap CI (norms in fp32, no-grad, EMA weights). **Baselines**: *minde\_comp* (three

separately trained MINDE MI terms composed as above), *MINE* and *InfoNCE* (lower-bound MI, same composition), *batch\_pid* (Liang et al. CVX PID, k-means  $k=20$  then max-entropy solve), and *broja/plugin* on  $d=1$ .

## Sweep progress

| Phase | Method     | Done | Expected |
|-------|------------|------|----------|

| mine           | 62     | 0.8132                             | 0.58     |
| infonce        | 62     | 3.9327                             | 0.37     |

## SynDiff vs prior — absolute error to truth $|\hat{S} - S|$ (nats)

Each entry is  $|\text{estimate} - \text{truth}|$  in nats; **bold** marks the most accurate method for that cell. ‘—’ means not yet computed.
