$S = I(X_1; Y | X_2) - I(X_1; Y)$ in nats; $S > 0$ synergy-dominant, $S < 0$ redundancy-dominant. SynDiff (ours) vs prior estimators.

Dataset construction

Phase 1 — Gaussian (closed-form ground truth)

Scalar base: $X_1, X_2 \sim \mathcal{N}(0, 1)$ with $\text{corr}(X_1, X_2) = \rho$; label $Y = X_1 + X_2 + \sigma_y \varepsilon$, $\varepsilon \sim \mathcal{N}(0, 1)$. Thus $\text{Var}(Y) = 2 + 2\rho + \sigma_y^2$ and $\text{Cov}(X_i, Y) = 1 + \rho$. To lift to d dimensions the informative scalar is padded with $d - 1$ i.i.d. $\mathcal{N}(0, 1)$ coordinates and rotated by a fixed per-seed orthogonal matrix Q_i (one per variable). Rotation and independent padding preserve mutual information, so S is unchanged and the closed form carries over. Ground truth is computed from the 3×3 covariance via $I = \frac{1}{2} \log(\det \Sigma_A \det \Sigma_B / \det \Sigma_{AB})$ and the analogous conditional form. Cells sweep $\rho \in \{-.9, \dots, .9\}$, $\sigma_y \in \{.1, 1\}$, $n \in \{1k, \dots, 100k\}$, $d \in \{1, 8, 32, 128\}$.

Phase 2 — discrete U/R/S (mixture-density MC truth)

Latent sources $s_1, s_2, s_3 \sim \text{Unif}\{0, \dots, Q - 1\}$ with $Q = 8$. Encodings $X_i = W_i \text{onehot}(s_i) + \sigma_{\text{enc}} \mathcal{N}(0, I_{32})$ with orthonormal $W_i \in \mathbb{R}^{32 \times 8}$ frozen per seed. Regimes (X_1 always encodes s_1): **UNIQUE** $Y = s_1$; **REDUNDANT** $Y = s_1$ and X_2 also encodes s_1 ; **SYNERGY1** $Y = (s_1 + s_2) \bmod Q$ with $X_2 \sim s_2$; **SYNERGY2** $Y = (s_3 + (s_1 + s_2) \bmod Q) \bmod Q$ with $X_2 = [\text{enc}(s_2) | \text{enc}(s_3)] \in \mathbb{R}^{64}$; **INDEPENDENT** $Y = s_3$. The λ -dial mixes the SYNERGY1 and REDUNDANT rules per sample (Bernoulli(λ)). Ground truth is the exact $S = I(X_1; X_2, Y) - I(X_1; X_2) - I(X_1; Y)$ obtained by Monte Carlo over the enumerable Gaussian-mixture components (matches the discrete limit as $\sigma_{\text{enc}} \rightarrow 0$: $\pm \log Q$ for pure synergy/redundancy, 0 for unique/independent).

Method: SynDiff

Target $S = I(X_1; Y | X_2) - I(X_1; Y)$ in nats. By the symmetry of interaction information this equals $I(X_1; X_2 | Y) - I(X_1; X_2)$, which the four-mask form below estimates directly. **VP schedule:** $\beta(t) = 0.1 + 19.9t$, $B(t) = \int_0^t \beta = 0.1t + 9.95t^2$, signal $k(t) = e^{-B/2}$, noise $\sigma^2(t) = 1 - e^{-B}$, weight $w(t) = \beta(t)/(2\sigma^2(t))$. A single noise-prediction network $\hat{e}(x_{1,t}, t, \text{cond})$ (*MaskedCondMLP*: Fourier- t features $\oplus$ per-slot conditioning embeddings each with a learned NULL token; 4×512 SiLU) is trained to denoise X_1 while each conditioning slot (X_2, Y) is independently dropped to its NULL token with probability 0.15. EMA weights (decay 0.999) are used at evaluation. **Four-mask estimator.** Per evaluation triple and per stratified time t ($K=16$ strata on $[10^{-3}, 1]$) with *one shared* noise draw ε and $x_{1,t} = k(t)x_1 + \sigma(t)\varepsilon$:

$$\begin{aligned} e_1 &= \hat{e}(x_{1,t}, t, x_2, y), & e_2 &= \hat{e}(x_{1,t}, t, \emptyset, y), \\ e_3 &= \hat{e}(x_{1,t}, t, x_2, \emptyset), & e_4 &= \hat{e}(x_{1,t}, t, \emptyset, \emptyset), \end{aligned}$$

$$\text{integrand}(t) = w(t)(\|e_1 - e_2\|^2 - \|e_3 - e_4\|^2).$$

Per-sample $\hat{S} = (1 - 10^{-3}) \overline{\text{integrand}_t}$; the estimate is the mean over 10^4 fresh triples with a 1000-sample bootstrap CI (norms in fp32, no-grad, EMA weights). **Baselines:** *minde_comp* (three

separately trained MINDE MI terms composed as above), *MINE* and *InfoNCE* (lower-bound MI, same composition), *batch_pid* (Liang et al. CVX PID, k-means $k=20$ then max-entropy solve), and *broja/plugin* on $d=1$.

Sweep progress
